Abstract

Tamarind (Tamarindus indica) is a versatile plant, findable in Indonesia (Java, Bali, North Sumatra, West Kalimantan, and South Sulawesi). The leaves are green to brown, round, 1-2.5 cm long and 4-8 mm wide, rounded tips, rounded base of blades, and flat edges. The content contained in tamarind leaves such as flavonoids, tannins, saponins, and alkaloids is believed to inhibit Propionibacterium acnes activity. This study aims to determine the effect of tamarind leaf extract ointment in controlling the growth of the bacteria Propionibacterium acnes that triggers acne. This study applied a Completely Randomized Design with 96% ethanol maceration method. Propionibacterium acnes was evidenced by the inhibition zone formed. The diameter of the inhibition zone of the 25% ointment was 1.235 cm, the 30% concentration was 1.385 cm, the 35% concentration was 1.680 cm, and the ointment base was 0 cm. The ANOVA test showed a significant value of 0.000<0.05, so there was a significant difference between the inhibition zone and the 95% confidence level. The results of Post Hoc test were P<0.05, meaning that there was a significant difference between the bases with formulas 1, 2, and 3. Thus, tamarind leaf extract ointment had a strong inhibitory effect on Propionibacterium acnes.

Keywords: Tamarind; Ointment; Acne; Propionibacterium acnes

INTRODUCTION

Skin health is something that is considered very important for everyone, especially teenagers. Therefore, they compete to always maintain healthy skin to avoid skin diseases. One of the problems with skin health is acne (Lestari et al., 2021). Acne (Acne vulgaris) is a skin disorder caused by Staphylococcus aureus and Propionibacterium acnes bacteria. This disorder can affect anyone, especially those aged 14-30 years. Acne can also be interpreted as a disorder in the form of inflammation that occurs in the pilosebaceous layer in line with the accumulation and blockage of keratin material, one of which is caused by the bacterium Propionibacterium acnes (Herawati & Amelia, 2018; Marliana et al., 2018). It causes problems for humans who want clean and smooth skin. It is evidenced by the increasing trend of using skincare among teenagers, especially skincare to prevent and treat acne.

Acne can be treated by using drugs that contain antibiotics, but drugs that are not in accordance with the rules of antibiotics will make the bacteria experience resistance (Herawati & Amelia, 2018). For this reason, people must be very careful in choosing acne medications because drugs that are widely circulated are proven to contain synthetic chemicals, such as azelaic acid and benzoyl peroxide. Azelic acid and benzoyl peroxide can cause irritation side effects, while long-term use can cause resistance. These ingredients have a worse impact than natural ingredients (Soemarie et al., 2017).

The way that can be taken to prevent side effects from using drugs containing synthetic ingredients that can cause irritation and resistance is to use herbal ingredients for acne treatment. The benefits of herbal medicines are also diverse, such as the price is quite affordable, easy to obtain, and has fewer side effects. This reason ultimately makes people prefer this type, especially those from plants (Herawati & Amelia, 2018; Winato et al., 2019). Even the process of processing herbal medicines is now increasingly following technological developments and what is currently being developed is the manufacture of extracts (Puspodewi et al., 2015; Zai et al., 2019).

Tamarind is an alternative plant that is used as herbal medicine from many types of plants. Tamarind is a plant commonly found in tropical areas, including Indonesia. Based on Faradiba et al., (2016), tamarind is classified as a versatile plant because the leaves, stems, fruit, and seeds can be used. However, the
benefits of tamarind plants that are seen by the community are as a kitchen spice (Faradiba et al., 2016).

One part of tamarind that is widely used is the leaves, which can be used as cooking spices, medicinal ingredients, and also cosmetic ingredients (Lahama et al., 2017). Antibacterial, antifungal, anti-inflammatory, and antioxidant activities can be found in the extract from tamarind leaves (Judge & Keumala, 2016). In addition, tamarind leaves also store some content such as protein, saponins, phosphorus, fat, fiber, tannins, taurine, alkaloids, flavonoids, minerals (such as sodium, potassium, magnesium, calcium), and others. Not only that, the content of secondary metabolites in tamarind leaf extract, namely flavonoids, tannins, alkaloids, and saponins can provide antibacterial properties (Nasution & Abdifi, 2013).

Tamarind leaves contain substances that can cure various diseases and inhibit bacterial activity. According to Puspodewi et al., (2015), if tamarind leaves are processed further, such as extracted using maceration or infusion, then tamarind leaves will have antibacterial power against Salmonella typhi bacteria. Based on research results Suryadi et al., (2015), tamarind leaf liquid preparation has antibacterial activity against Escherichia coli. In addition, ethanol extract from tamarind leaves which have a concentration of 20%, 40% concentration, 60% concentration, 80% concentration, up to 100% concentration can inhibit the growth of Escherichia coli and Staphylococcus aureus (Multazami, 2013). However, there has been no research on the antibacterial activity of tamarind leaves (Tamarindus indica) against the bacteria Propionibacterium acnes which is the main bacteria that causes acne.

Researchers tested the effect of an ointment made from extracts from tamarind leaves on the diameter of the inhibition zone of the bacteria Propionibacterium acnes that triggers acne. According to Ulaen et al., (2012), the product in the form of an ointment was chosen because the ointment has a good consistency for skin diseases caused by bacteria. This ointment formulation is used to provide ease of use and provide the desired effect by the user. Ointment will be more suitable to be applied to acne. The active substance can also be removed by PEG-based ointment preparations better than other oil-soluble bases. This base is also suitable for acne-prone skin because it does not contain oil (Ulaen et al., 2012).

Thus, this is an effort to optimize and utilize the potential contained in tamarind leaves (Tamarindus indica) as a natural
component in the manufacture of ointment products and conduct research on the effect of the ointment on the diameter of the zone of *Propionibacterium acnes* that triggers acne in the middle. increasing trend of using skincare for the prevention and treatment of acne.

**MATERIALS AND METHODS**

This research is a quantitative research with experimental method. The research was conducted at the Microbiology Laboratory of Biology Education and at the Central Laboratory of the Chemistry Sublab at Sebelas Maret University in August 2021 for one month. In this study, the data were presented in tabulated form and statistically analyzed using IBM SPSS Statistics 26 with One Way Anova test and followed by Post Hoc test to compare the treatment inhibition zones between test groups. Testing of antibacterial activity refers to Cahyanta & Ardiyanti’s study (2018) with modification. Preparation of ointment from ethanolic extract of tamarind leaves against *Propionibacterium acnes* was carried out in vitro with growth media in the form of nutrient agar by analogy measuring the diameter of the inhibition zone using a ruler. The negative sample in this study was an antibacterial test using an ointment without the addition of tamarind leaf extract, while the positive sample used an tamarind leaf extract ointment with concentrations of 25%, 30%, and 35%. The research technique consisted of 4 treatments with 20 replications. The sample in this study consisted of 5 petri dishes with 4 parts in each petri dish containing *Propionibacterium acnes* bacteria.

**Preparation of Tools and Materials**

The tools needed were beaker, erlenmeyer, measuring cup, analytical balance, magnetic stirrer, stirrer bars, oven, autoclave, water bath, ose needle with round needle tip, petri dish, blender, rotary evaporator, refrigerator, ointment pot. size 30 cc, mixer, micropipette, bunsen, spirtus, cotton buds, scissors, cutter, ruler, aluminum foil, HDPE plastic Torch brand size 20x35 cm, plastic jars, plastic wrapping, markers, lighters, and paper labels. The materials needed are tamarind leaves (*Tamarindus indica*), bacterial culture isolate *Propionibacterium acnes* 100 ml liquid media, 96% ethanol Merck brand, 5 L aquadest, 50 grams nutrient agar for Merck brand, PEG-4000, PEG -400, nipagin, citri oleum, filter paper, disc paper, and cotton.
Making Tamarind Leaf Extract

Extraction based on Cahyanta & Ardiyanti’s procedure (2018) with modification. Maceration method with 96% ethanol extract was used in the process of making leaf extract. The tamarind leaf simplicia powder was weighed until it reached a weight of 145 grams and soaked in 725 ml of 96% ethanol, then stirred using a magnetic stirrer for 3 hours per day for 5 days. Filter paper was used as a filtration medium in both the first and second stages. The whole maserate was then concentrated using a rotary evaporator at 60°C with a speed of 500 rpm.

Source: Research primary data (2021)

The first step in making the ointment was to dissolve nipagin in PEG-400. Then PEG-4000 was put into a mixture of nipagin and PEG 400 on a water bath and stirred until it cooled. Tamarind leaf extract that has been made is put into the mixture and then stirred until homogeneous. Next, added oleum citri little by little in the mixture until evenly distributed. After that, the ointment was stored in the ointment pot.

Nutrient Agar Media Preparation

The growth medium was made by diluting nutrient agar 20 grams in 1 liter of distilled water in an Erlenmeyer tube, then covered with aluminum foil. The mixture was homogenized using a magnetic stirrer. Next, the mixture was sterilized using an autoclave at 121°C.
Growth of Bacterial Subculture Test of Propionibacterium acnes

The test bacteria were cultured in nutrient media to make them sterile. A total of 10 mL of media was inoculated into sterile petri dishes and allowed to solidify. Bacterial subculture was performed with a spread plate. 0.1 mL of bacteria was poured using a micropipette and then flattened with a spreader.

The Potential of Tamarind Leaf Extract Ointment in Inhibiting the Growth of Propionibacterium acnes Bacteria

After pure bacterial cultures were grown on nutrient agar media, the paper discs that had been smeared with ointment from tamarind leaf extract were placed on top. Next, the media was incubated for 24 hours at a temperature of 37°C. Observations and measurements of the clear zone were carried out using a ruler (Cahyanta & Ardiyanti, 2018; Lajira et al., 2019). Tests for ointments from tamarind leaf extract used various concentrations of 25%, 30%, and 35%. The negative control was an ointment based without tamarind leaf extract.

Research and Data Collection

The parameters tested in this study were the diameter of the inhibition zone of tamarind leaf extract ointment with different levels of extract as the independent variable and growth media in the form of nutrient agar as the dependent variable. Measuring the diameter of the inhibition zone using a ruler.

RESULTS AND DISCUSSION

The extract produced from tamarind leaves (Tamarindus indica) has a thick texture with a dark green color and weighs 10 grams. This test indicates a clear area around the disc. The area was the inhibition zone for the growth of Propionibacterium acnes bacteria which has been treated with tamarind leaf extract ointment.

Figure 1. Inhibition Zone of Tamarind Leaf Extract Ointment (0%)
Source: Research primary data (2021)
The formulation obtained from the test results of the antibacterial treatment of tamarind leaf extract ointment had the largest inhibition zone in formula 3 (35%) with an average inhibition zone diameter of 1,680 cm. Measurement of the diameter of the largest inhibition zone in formula 3 (35%) showed that the ointment had a strong range of inhibition against Propionibacterium acnes bacteria. Pan et al., (2009) stated that the inhibition zone...
criteria were determined as follows: an area with an inhibition zone diameter of 5-10 mm that has a diameter of inhibition zone ≥20 mm was categorized as very strong, areas with an inhibition zone diameter of 10-20 mm were categorized as strong, then areas with an inhibition zone diameter of 5-10 mm were included in the weak category.

The test results showed that the significant value of 0.000 < 0.05 so that there was a significant difference in the inhibition zone of each ointment formula. Therefore, extracts from Tamarindus indica leaves at concentrations of 25%, 30%, and 35% were able to affect the metabolism of Propionibacterium acnes bacteria.

One Way ANOVA analysis (Table 2) with a 95% confidence level (α = 5%) had a significant value of 0.000 < 0.05 so that there was a significant difference in the inhibition zone of each ointment formula. Furthermore, the Post Hoc Tests follow-up which aims to compare the treatment inhibition zones between the test groups with significant values obtained the following results.

Source: Research primary data (2021)
Post Hoc follow-up test values indicated that there was a clear difference in antibacterial activity between the bases with formula 1, formula 2, and formula 3 because $P < 0.05$.

The antibacterial activity of tamarind leaf extract ointment (Tamarindus indica) occurred due to the presence of compounds that had antibacterial properties, such as flavonoids which had antibacterial activity in the form of functional barriers to DNA gyrase, so that the ability to replicate bacteria was inhibited. This compound was in contact with DNA in the nucleus of bacterial cells. The difference in polarity between the lipids that made up DNA and the alcohol groups in flavonoid compounds caused damage to the lipid structure of bacterial DNA so that the bacteria underwent lysis and died. Alkaloids as antibacterial interfered with the peptidoglycan constituent components in bacterial cells so that the cell wall layer could not be fully formed and cell death occurred (Cahyanta & Ardiyanti, 2018). The next content of tamarind leaves is saponins. Saponins are included in the antibacterial group that interfere with the permeability of the bacterial cell membrane so that it will damage the cell membrane and cause the release of various vital elements from the antibacterial cell in the form of proteins, nucleic acids, and nucleotides, so that the bacteria will undergo lysis.

The results of the phytochemical identification carried out on tamarind leaves extract showed the presence of active compounds in the form of saponins, flavonoids, and tannins (Nasution & Abdifi, 2013). Hakim & Keumala (2016) mentioned that there were antibacterial, antifungal, anti-inflammatory, and antioxidant activities in tamarind leaf extract. There are fiber, fat, protein, taurine and alkaloids, saponins, tannins, flavonoids, minerals (eg sodium, potassium, magnesium, phosphorus, calcium), and others in tamarind leaves. In addition, there were many vitamins such as thiamine (vitamin B1), pectin, riboflavin (vitamin B2), -carotene (vitamin A), ascorbic acid (vitamin C), and niacin (vitamin B3 or B complex). The content of secondary metabolites contained in tamarind leaf extract in the form of flavonoids, tannins, saponins, and alkaloids that provide antibacterial properties in tamarind leaves (Yunita & Khodijah, 2020).

**CONCLUSION**

Ointment from tamarind leaf extract with concentrations of 25%, 30%, and 35% was proven to have antibacterial activity against *Propionibacterium acnes* bacteria. The results of the calculation of the
diameter of the inhibition zone stated that the ointment from the extract of the leaves of tamarind (Tamarindus indica) had a strong category of inhibition against the bacteria Propionibacterium acnes.
